### Description:

The \_ACTIVEPOLLS dictionary contains all the Poll objects and represents active polls. The dictionary itself and the POLLNUMBER counter guarantee the uniqueness of the polls.

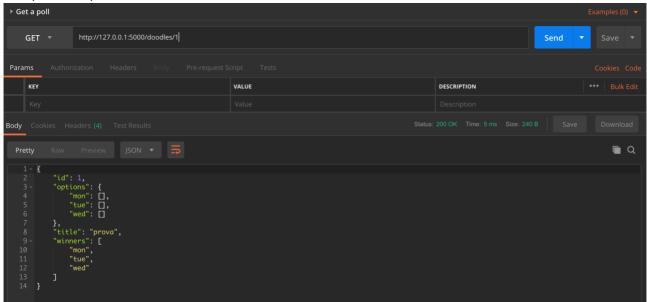

- 1. *all\_polls()*: handles operations over the entire collection of polls. It implements '/doodles' endpoint handling the following HTTP methods:
  - a. GET: returns the list of currently active polls
  - b. POST: create a new poll reading data from the JSON body of the request and add the new object to the ACTIVEPOLLS dictionary using the POLLNUMBER counter as index.
- 2. *single\_poll(id)*: handles operations on a single poll. The endpoint decoration converts the id into an integer and allow the following HTTP methods:
  - a. GET: simply returns the JSON representation of the poll at position *id* in the ACTIVEPOLLS dictionary.
  - b. DELETE: removes from the \_ACTIVE\_POLLS dictionary the poll at position id using *pop* method.
  - c. PUT: handles the vote operation on a specific poll implemented by the function vote which simply read from the request the person who vote and the option and update the Poll instance. If the option doesn't exist, a NonExistingOptionException is thrown and the service reply with status code 400, as the client provided invalid data to the service.
- 3. *person\_poll(id, person)*: handles operations over a poll done by a person. The endpoint decoration converts id to an integer and the person identifier as a string. The allowed HTTP methods are:
  - a. GET: returns a (jsonified) dictionary with the voted options by the selected person
  - b. DELETE: returns a (jsonified) dictionary whose key 'removed' is set to True whether the votes of the selected person have been removed.

#### Pytest result:

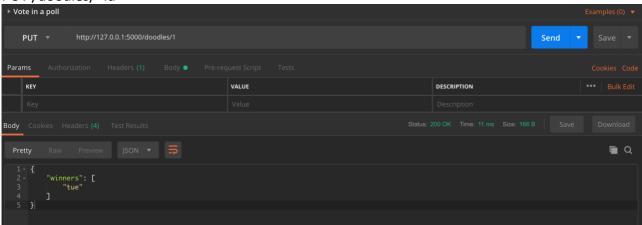

### POST /doodles

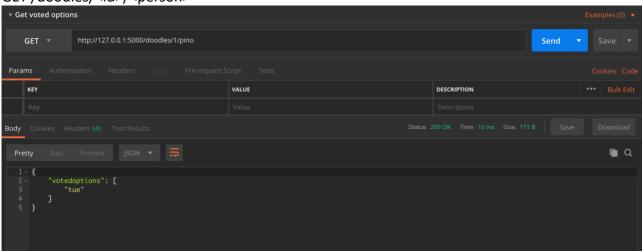

# GET /doodles/<id>

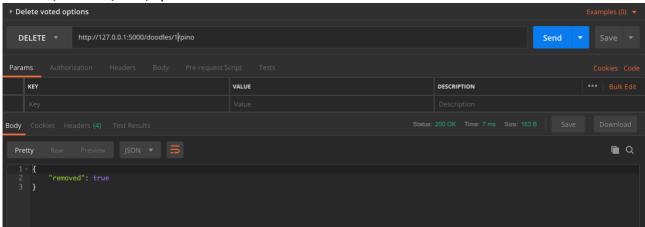

## PUT /doodles/<id>

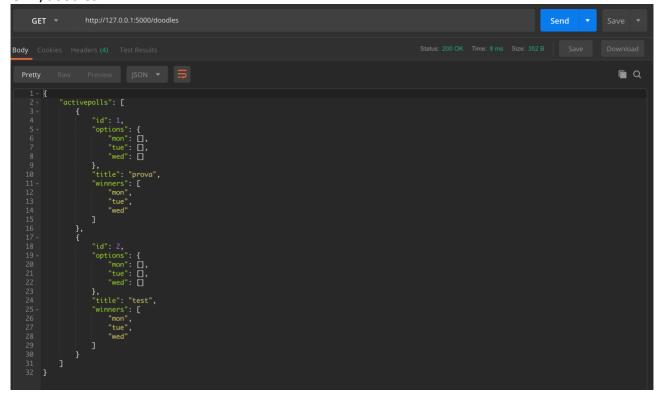

## GET /doodles/<id>/<person>

DELETE /doodles/<id>/<person>

## GET /doodles

DELETE /doodles/<id>
